Wanilla
Eyre Peninsula Groundwater Dependent Ecosystems monitoring site

2019 Report Card

Summary

Type of site: Licensed extraction monitoring site.
Status: Green, positive trend in the short term (2016 to 2019).

Red Gums: Getting better

Ground water levels: Declining

Climate: Above average maximum temperatures and declining annual rainfall and recharge events.

This Report Card should be read in conjunction with the Overview, which provides information about Groundwater Dependent Ecosystem (GDE) monitoring and summary information for all monitored GDE sites.

The Wanilla Ground Water Dependent Ecosystems monitoring site is situated four kilometres east of the Coffin Bay road turn off on Flinders Highway. The site is part of a large remnant patch of Red Gum (Eucalyptus camaldulensis) Woodland. Amongst the Red Gum overstorey and midstorey grows native apricot (Pittosporum sp.), hop-bush (Dodonaea sp.), coast beard-heath (Leucopogon sp.) and sheoak (Allocasuarina spp.).

The Wanilla site is a licensed extraction GDE site, monitored to assess the impacts of licensed extractions. Located in a licensed extraction area, there are a number of users (including SA Water) who hold licenses to use a limited amount of water for drinking water supply and other private commercial purposes. Access to water extraction details can be found on WaterConnect in the relevant 2018 Groundwater level and salinity status report.

While there is unlicensed extraction of water for stock and domestic purposes, this is assumed to be low compared to extraction for licensed consumptive purposes at other sites, and there is a low likelihood of it having any impact on the GDE.

Red Gum condition

Tree condition monitoring was undertaken in 2016 and repeated in 2018 and 2019. In 2016 the average Red Gum Condition Index (RCI) score was 0.47, increasing to 0.52 in 2019. While this shows a 5% improvement in Red Gum condition over this three year period, the dataset is too short to enable determination of any long term trends.
Groundwater and climate assessment

Improvement in Red Gum condition was observed from 2016 to 2019 despite possible increased stress due to climate variability.

Graphs on the right show climatic factors contributing to Red Gum stress:
- In the short term (2016 to 2019) total annual rainfall has decreased from 670.5 mm in 2016 to 358.0 mm in 2019, with an associated decline in groundwater levels. Large drops in water levels at WNL47 at the start of each year are due to this well being next to a production bore.
- Graph 2 shows in the long term, there is also a decline in total winter (May to September) rainfall (blue line). Daily rainfall events of more than 10 mm in winter (between May and Sept) are also in decline (orange line). These events are likely to be the main cause of recharge to groundwater and are thought to be significant for long-term Red Gum health (Graph 2).

In addition, the average annual maximum air temperature at Port Lincoln has increased by 1.2 degrees Celsius between 1962 and 2019.

In combination, this decreasing rainfall and increasing temperatures reduce water availability for Red Gums. Less water is immediately available from rainfall, there is more evaporation, and there is a reduction in groundwater recharge. Groundwater levels can therefore decline, and this is thought to be significant for long-term Red Gum health.

Monitoring into the future

Tree condition monitoring will continue on a yearly basis. As time goes on more data will allow for the identification of any trends in the GDE condition.

New monitoring infrastructure was installed at Wanilla in 2019 to improve the site specific accuracy of data collection. Additions include:
- one additional monitoring well,
- a water level data-logger at one well, and
- a rain gauge to measure rainfall intensity and amount.
